Demystifying Boot Disks

Eli Billauer

eli@billauer.co.il

Lecture's outline

- Introduction
- The RAM disk and the loop device
- What's in a rescue disk
- What you need to know to successfully modify a rescue disk
- What's in a boot disk, and how to modify it

General remark: A large part of this lecture is example-oriented. Where an example is given the explanations are omitted from the slides

Why boot/rescue disks?

The general idea: Running Linux without mounting hard disks

- Repairing a damaged system ("rescue" disks)
- Running Linux for a single ad-hoc application
- Running on a diskless computer
- Trying a newly compiled kernel

Where to find what

- Documentation
  - Bootdisk-HOWTO
  - BootPrompt-HOWTO
  - The LILO mini-HOWTO
  - `/usr/src/linux/Documentation/ramdisk.txt`
  - `/usr/src/linux/Documentation/initrd.txt`
  - `/usr/src/linux/init/main.c` (Source code of boot process)
- Boot images
  - On installation CD's, typically under `images/`
  - All over the web

What happens when you boot

- The kernel is loaded, uncompressed and run
- The kernel *might* do some Hocus-Pocus (explained later) to run a `linuxrc` initialization executable
- The kernel mounts a root directory on a device, usually known in advance
- The First Process is launched, trying in the following order: `/etc/init`, `/bin/init`, `/sbin/init` or other defaults.
- The boot is now in the hands of this process.

As we shall see, there are endless variations for this

Different ways to boot up

- From hard disk
- Boot kernel from floppy, root on hard disk
- Boot kernel from floppy, root on floppy disk
- Boot kernel from floppy, root on **RAM disk**.
  - The root image comes from boot disk
  - The root image comes from a second disk
  - Both...
- Booting from CD-ROM is actually booting a floppy disk image written on CD. (See `mkisofs` documentation)
- `loadlin.exe` (used by linux4win)

The RAM disk

This will create a 4 Mbyte RAM disk, and mount it.

```
# dd if=/dev/zero of=/dev/ram0 bs=1k count=4096
4096+0 records in
4096+0 records out
# mke2fs /dev/ram0
mke2fs 1.10, 24-Apr-97 for EXT2 FS 0.5b, 95/08/09
(...)
# mkdir /mnt/ram
# mount /dev/ram0 /mnt/ram
```

The RAM disk (cont.)

- After these instructions ,we can use `/mnt/ram` like any usual disk.
- The memory taken by a RAM disk is never returned (reboot...)
- This is implicitly done by the kernel when we boot into a RAM disk but:
  - The kernel copies the boot image from floppy to RAM disk. Something like:

    ```
    cat /dev/fd0 | zcat > /dev/ram0
    ```

  - Then the kernel mounts the image as root directory.

The loop device

How to create a 1 MB loop disk

```
# dd if=/dev/zero of=loopfile bs=1024 count=1024
1024+0 records in
1024+0 records out
# ls -l loopfile
-rw-rw-r--   1 root root  1048576 Dec 14 22:32 loopfile
# mke2fs loopfile
mke2fs 1.10, 24-Apr-97 for EXT2 FS 0.5b, 95/08/09
loopfile is not a block special device.
Proceed anyway? (y,n) y
(...)
# mkdir mountdir
# mount -o loop loopfile mountdir
```

The loop device (cont.)

- Note that `mount -o loop` is actually an abbreviation for

```
# losetup /dev/loop0 loopfile
# mount /dev/loop0 mountdir
```

- ...except that `mount` looks for an available loop device (`/dev/loop0, /dev/loop1, ...`)
- Loop devices depend on the `loop.o` kernel module

Exploring the rescue disk

- If we want to see what's in a certain diskette, we first raw-copy it to a file:

```
# cat /dev/fd0 > from-diskette.gz
# gunzip from-diskette.gz

gunzip: from-diskette.gz: decompression OK,
trailing garbage ignored
```

- Using `cat` to raw-read diskettes is "politically incorrect", so it's more common to see is the equivalent

```
# dd if=/dev/fd0 of=from-diskette.gz bs=1k
```

- We next look at the rescue disk image which comes with the installation CD.

Exploring the rescue disk (cont.)

```
# cp /mnt/cdrom/images/rescue.img rescue.gz
# ls -l rescue.gz
-r--r--r--   1 root  root  1401934 Dec 15 01:11 rescue.gz
# gunzip rescue.gz
# ls -l rescue
-r--r--r--   1 root  root  4194304 Dec 15 01:11 rescue
# mkdir temp
# mount -o loop rescue temp
# cd temp
# ls -F
bin/         lib/         proc/        usr/
dev/         lost+found/  sbin@
etc/         mnt/         tmp/
```

Exploring the rescue disk (cont.)

```

```

Changing the rescue disk

What we'll talk about:

- Creating a initrd disk image
- Dynamic linking
- Kernel Modules
- Adding a `/dev` device

Creating an initrd RAM disk image

After adding and/or removing the files, wrap it all up by:

```
# umount temp
# gzip rescue
# cat rescue.gz > /dev/fd0
```

Size considerations:

- If you modify an existing RAM disk image, you can't exceed the allocated file system size.
- You may create a bigger filesystem of your own, and tell the kernel to prepare a larger RAM disk with the `ramdisk_size=` kernel argument.
- The bigger problem is to fit the gzipped file into a floppy disk.

Dynamic Linking

- If you want to add an executable to your rescue disk, make sure the libraries are there too!

```
# ldd /sbin/ifconfig
    libc.so.6 => /lib/libc.so.6 (0x40006000)
    /lib/ld-linux.so.2 => /lib/ld-linux.so.2 (0x00000000)
```

- We then need to verify that the libraries exist, for example:

```
# ls -l /lib/libc*
(...)  root  root  /lib/libc-2.0.7.so*
(...)  root  root  /lib/libc.so.6 -> libc-2.0.7.so*
(...)
```

Dynamic Linking (cont.)

- Dynamic linking can be bypassed by compiling the source with `gcc -static ...`
- This creates an independent executable

Kernel Modules

- If you add a new executable, it might require a specific kernel module. `lsmod` might help to find out which.
- Kernel modules might be implicitly needed to access file systems, hardware, etc.
- There's no automated way to know which modules you'll need
- There will (probably) be no `kerneld` running in rescue mode.
- There are two ways to get the modules in place, then:
  - Copy the modules into the rescue disk and `insmod` as needed.
  - Have all possibly needed modules loaded from the **boot disk**. (You won't waste your precisous rescue disk space on this!)

Kernel Modules (cont.)

- The kernel modules are organized under `/lib/modules`. The directory structure goes deep
- Some modules depend on others. Attempting to `insmod` a module before a module it depends on will result in an error message regarding unresolved symbols.
- A quite easy-to-understand makefile-type list of module dependencies appears in the `modules.dep` file, typically `/lib/modules/preferred/modules.dep`. This file is created by the `depmod` command.

Adding a /dev device

```
# ls -l /dev/hda*
brw-rw----   1 root  disk  3,  0 May  5  1998 /dev/hda
brw-rw----   1 root  disk  3,  1 May  5  1998 /dev/hda1
brw-rw----   1 root  disk  3,  2 May  5  1998 /dev/hda2
...

# ls -l /dev/ttyS*
crw-r--r--   1 root  root  4, 64 May  5  1998 /dev/ttyS0
crw-r--r--   1 root  root  4, 65 May  5  1998 /dev/ttyS1
crw-r--r--   1 root  root  4  66 May  5  1998 /dev/ttyS2
crw-r--r--   1 root  root  4, 67 May  5  1998 /dev/ttyS3
```

Adding a /dev device (cont.)

Now we'll demonstrate how to add a loop device to our rescue disk

- First we find out the type, major and minor of the device:

```
# ls -l /dev/loop0
brw-rw----   1 root  disk  7, 0 May  5  1998 /dev/loop0
```

- Aha! It's a block device with major 7 and minor 0. We can now create one on the boot disk.

```
# mknod /mnt/my-rescue-disk/dev/loop0 b 7 0
```

- A list of majors and minors can be found in `/usr/src/linux/Documentation/devices.txt` (try also `/usr/src/linux/include/linux/major.h`)

Don't say I didn't warn you

Dealing with boot & rescue disks should be harmless, but there are plenty of ways to screw up your system while playing with them:

- Write to `/dev/hda` instead of `/dev/fd0`
- Tamper with your system files instead of your image files
- You are root most of the time. Plenty of chances to do stupid things.

Exploring the boot disk

There are two kinds of boot disks:

- Kernel and boot image raw-written on sectors (yuck!)
  - The old way to create boot disks
  - Disk is setup with `rdev`
  - We won't get into this further
- Disk contains an ext2 file system and is LILO'ed
  - The kernel and boot image appear as files
  - The file system is there only so that the `lilo` executable will have a correct environment.
  - Kernel arguments may be sent during bootup, as usual

Exploring the boot disk (cont.)

We now look at a **customized** boot disk

```
# mount /dev/fd0 /mnt/floppy
# cd /mnt/floppy
# ls -RF
.:
boot/  etc/         lost+found/
dev/   initrd.img   vmlinuz-2.2.14-15mdk
boot:
boot.0200  boot.b  map  message
dev:
fd0  hda7
etc:
lilo.conf
```

Exploring the boot disk (cont.)

```
# cat etc/lilo.conf
boot=/dev/fd0
timeout=100
message=/boot/message
prompt
image=/vmlinuz-2.2.14-15mdk
     label=linux
     root=/dev/hda7
     append=" hdc=ide-scsi "
image=/vmlinuz-2.2.14-15mdk
     label=rescue
     append="load_ramdisk=2 prompt_ramdisk=1 hdc=ide-scsi"
     root=/dev/fd0
     initrd=/initrd.img
```

Exploring the boot disk (cont.)

Did I just count **TWO** RAM disks?

- The kernel is booted from the boot disk
- `initrd.img` is uncompressed and loaded into the RAM disk, which is mounted as root
- `/linuxrc` is executed
- The kernel prompts for a second disk
- The RAM disk is now loaded from `/dev/fd0` (compressed raw data, as we saw before). This is the "rescue disk"
- Root is **remounted** with the new RAM disk.
- `/etc/init`, `/bin/init`, or `/sbin/init` is executed, whichever is found first.

Exploring the boot disk (cont.)

We now look at the RAM disk image on the **boot disk**

```
# cp initrd.img ~/
# cd ~/
# mv initrd.img initrd.gz
# gunzip initrd.gz
# mkdir rd
# mount -o loop initrd rd
```

Exploring the boot disk (cont.)

```
# ls -rF rd
linuxrc*  lib/  etc/  dev/  bin/
# ls -RF rd
rd:
bin/  dev/  etc/  lib/  linuxrc*
rd/bin:
insmod*  sh*
rd/dev:
console  null  ram  systty  tty1  tty2  tty3  tty4
rd/etc:
rd/lib:
fat.o       lockd.o  ntfs.o  slhc.o    supermount.o
ide-scsi.o  msdos.o  ppp.o   sunrpc.o  vfat.o
```

Exploring the boot disk (cont.)

The `linuxrc` file:

```
#!/bin/sh
echo "Loading ide-scsi module"
insmod /lib/ide-scsi.o
echo "Loading fat module"
insmod /lib/fat.o
echo "Loading vfat module"
insmod /lib/vfat.o
...
echo "Loading lockd module"
insmod /lib/lockd.o
```

Exploring the boot disk (cont.)

Hey! I didn't see any link libraries!

```
# ldd rd/bin/sh
        not a dynamic executable
# ldd rd/bin/insmod
        not a dynamic executable
```

- Both `sh` and `insmod` are statically linked, to avoid having the entire libraries.
- These files can probably be found in your filesystem as `/bin/ash.static` and `/sbin/insmod.static`

Changing the boot disk

- You might want to create your own with `mkbootdisk`
  - It's recommended to edit the `mkbootdisk` script so it adds the modules you want, rather than guessing them
  - Most of the script deals with picking the right modules. If you skip that part, and just choose the modules, it's quite easy
- If you want to add modules by hand, it's only a matter of adding the module in the `lib` directory, and modifying `linuxrc` accordingly.
- Be sure to load the modules in the right order!
- When finished, write the new compressed initrd.img to your floppy, **and run LILO**
